(57) **ABSTRACT**

A wireless power transmission and charging system and method are provided. The wireless power may refer to energy that may be transferred from a wireless power transmitter to a wireless power receiver. The wireless power transmission and charging system may include a source device to wirelessly transmit power, and a target device to wirelessly receive power.

WIRELESS POWER TRANSMISSION AND CHARGING SYSTEM, AND IMPEDANCE CONTROL METHOD THEREOF

CROSS-REFERENCE TO RELATED APPLICATION(S)

This application claims the benefit under 35 U.S.C. §119 (a) of Korean Patent Application No. 10-2011-0046654, filed on May 18, 2011, in the Korean Intellectual Property Office, the entire disclosure of which is incorporated herein by reference for all purposes.

BACKGROUND

1. Field

The following description relates to a wireless power transmission and charging system, and an impedance control method thereof.

2. Description of Related Art

Wireless power transfer refers to energy that is transferred from a wireless power transmitter to a wireless power receiver, for example, using magnetic coupling. The wireless power receiver may charge a battery using the received energy. Typically, a wireless power transmission and charging system includes a source device to wirelessly transmit power and a target device to wirelessly receive the power. In this example, the source device is referred to as a wireless power transmitter and the target device is referred to as a wireless power receiver.

Typically the source device includes a source resonator, and the target device includes a target resonator. Magnetic coupling or resonance coupling may be formed between the source resonator and the target resonator thus allowing for the transfer of power.

SUMMARY

In one general aspect, there is provided an impedance control method of a wireless power transmitter configured to transmit power to a plurality of target devices, the method including generating power for charging by determining an impedance of a source resonator based on the number of the plurality of target devices, and adjusting a signal level of a direct current (DC) voltage to be supplied to a power amplifier based on the number of the plurality of target devices, transmitting the charging power to the plurality of target devices through magnetic coupling, and adjusting the impedance of the source resonator based on one or more of a reflected wave of the charging power, an amount of power received by each of the plurality of target devices, an amount of the charging power, and a transmission efficiency of the charging power.

The method may further comprise, prior to generating a charging power, transmitting a wake-up request message to the plurality of target devices, receiving response messages corresponding to the wake-up request message from the plurality of target devices, and detecting the number of the plurality of target devices based on the received response messages.

The adjusting of the impedance of the source resonator may be performed by controlling N matching switches to be powered ON and/or OFF, and the N matching switches may be connected to a plurality of capacitors and/or a plurality of inductors.

Each of the response messages may comprise one or more of a product type of a corresponding target device, manufacturer information of the corresponding target device, a prod-

2

uct model name of the corresponding target device, a battery type of the corresponding target device, a charging scheme of the corresponding target device, an impedance value of a load of the corresponding target device, information about a characteristic of a target resonator of the corresponding target device, information about a used frequency band of the corresponding target device, an amount of a power to be used for the corresponding target device, an intrinsic identifier of the corresponding target device, and product version information or standards information of the corresponding target device.

The generating of the charging power may comprise determining the signal level of the DC voltage to be supplied to, the power amplifier based on one or more of a product type of the corresponding target device, a manufacturer information of the corresponding target device, a product model name of the corresponding target device, a battery type of the corresponding target device, a charging scheme of the corresponding target device, an impedance value of the load of the corresponding target device, information about the characteristic of the target resonator of the corresponding target device, information about the used frequency band of the corresponding target device, and an amount of a power to be used for the corresponding target device.

The adjusting of the impedance of the source resonator may comprise calculating a voltage standing wave ratio (VSWR) based on a voltage level of the reflected wave, a level of an output voltage, and a level of an output current of a source resonator, controlling the N matching switches to be powered ON and OFF, in response to the VSWR being less than a predetermined, reference value, determining a tracking impedance having a power transmission efficiency above a predetermined threshold, and changing the impedance of the source resonator to the tracking impedance having the power transmission efficiency above the predetermined threshold.

The determining of the tracking impedance having the power transmission efficiency above a predetermined threshold may comprise performing the following operations a) through g) continuously for each of the N matching switches,

a) selecting at least one of the N matching switches based on a predetermined selection scheme;

b) changing the impedance of the source resonator to a selected impedance, by controlling the at least one selected matching switch to be powered ON;

c) transmitting the charging power;

d) transmitting, to the plurality of target devices, a command to request an input voltage value and an input current value of a target device, or a command to request a DC/DC output voltage value and a DC/DC output current value of the target device;

e) receiving, from each of the plurality of target devices, an input voltage value and an input current value of a rectification unit, or the DC/DC output voltage value and the DC/DC output current value;

f) calculating an amount of a power received by each of the plurality of target devices, based on the input voltage value and the input current value, or the DC/DC output voltage value and the DC/DC output current value; and

g) calculating a transmission efficiency of the charging power, based on an output voltage level and an output current level of the source resonator, and the amount of a power received by each of the plurality of target devices.

The predetermined selection scheme in the operation a) may correspond to a scheme of selecting matching switches so that the plurality of capacitors may be powered ON and OFF in a sequential order, beginning from a capacitor having a lowest capacitance value to a capacitor having a highest capacitance value, or a scheme of selecting matching

switches so that the plurality of capacitors may be powered ON and OFF in a sequential order, beginning from the capacitor having the highest capacitance value to the capacitor having the lowest capacitance value.

The predetermined selection scheme in the operation a) may correspond to a scheme of sequentially selecting M matching switches from the N matching switches, performing the operations b) through g) continuously for each of the M matching switches, and subsequently performing the operations b) through g) continuously for each matching switch, excluding the M matching switches from the N matching switches, M being less than N.

The predetermined selection scheme in the operation a) may correspond to a scheme of classifying the N matching switches into M groups, selecting one of the M groups based on the number of the one or more target devices, and sequentially selecting tracking frequencies included in the selected group, M being less than N.

In another aspect, there is provided a wireless power transmitter including a power converter configured to generate power used for communication or a charging power used for charging in a plurality of target devices, by converting a direct current (DC) voltage to be supplied to a power amplifier to an alternating current (AC) voltage using a resonance frequency, a source resonator configured to transmit, to a plurality of target devices, the generated power through magnetic coupling, and an impedance adjusting unit configured to adjust an impedance of the source resonator based on one or more of a reflected wave of the charging power, an amount of power received by each of the plurality of target devices, an amount of the charging power, and a transmission efficiency of the charging power.

The impedance adjustment unit may be configured to adjust the impedance of the source resonator by controlling N matching switches to be powered ON and OFF, and the impedance adjusting unit comprises the N matching switches which are connected to a plurality of capacitors and/or a plurality of inductors.

The wireless power transmitter may further comprise a control and communication unit configured to determine the impedance of the source resonator, and a signal level of the DC voltage to be supplied to the power amplifier based on the number of the plurality of target devices, and to control the impedance adjusting unit.

The control and communication unit may be configured to determine the signal level of the DC voltage to be supplied to the power amplifier, based on one or more of a product type of a corresponding target device, manufacturer information of the corresponding target device, a product model name of the corresponding target device, a battery type of the corresponding target device, a charging scheme of the corresponding target device, an impedance value of a load of the corresponding target device, information about a characteristic of a target resonator of the corresponding target device, information about a used frequency band of the corresponding target device, and an amount of a power to be used for the corresponding target device.

The control and communication unit may be configured to calculate a voltage standing wave ratio (VSWR) based on a voltage level of the reflected wave, a level of an output voltage, and a level of an output current of the source resonator, to control the N matching switches to be powered ON and OFF if the VSWR is less than a predetermined value, to determine a tracking impedance having a power transmission efficiency above a predetermined threshold, and to change the imped-

ance of the source resonator to the tracking impedance having the power transmission efficiency above the predetermined threshold.

The control and communication unit may be configured to perform the following operations a) through g) continuously for each of the N matching switches in order to determine the tracking impedance having the power transmission efficiency above the predetermined threshold,

a) selecting at least one of the N matching switches, based on a predetermined selection scheme;

b) changing the impedance of the source resonator to a selected impedance, by controlling the at least one selected matching switch to be powered ON;

c) transmitting the charging power;

d) transmitting, to the plurality of target devices, a command to request an input voltage value and an input current value of a target device, or a command to request a DC/DC output voltage value and a DC/DC output current value of the target device;

e) receiving, from each of the plurality of target devices, an input voltage value and an input current value of a rectification unit, or the DC/DC output voltage value and the DC/DC output current value;

f) calculating an amount of a power received by each of the plurality of target devices, based on the input voltage value and the input current value, or the DC/DC output voltage value and the DC/DC output current value; and

g) calculating a transmission efficiency of the charging power, based on an output voltage level and an output current level of the source resonator, and the amount of a power received by each of the plurality of target devices.

The predetermined selection scheme in the operation a) may correspond to a scheme of selecting matching switches so that the plurality of capacitors may be powered ON and OFF in a sequential order, beginning from a capacitor having a lowest capacitance value to a capacitor having a highest capacitance value, or a scheme of selecting matching switches so that the plurality of capacitors may be powered ON and OFF in a sequential order, beginning from the capacitor having the highest capacitance value to the capacitor having the lowest capacitance value.

The predetermined selection scheme in the operation a) may correspond to a scheme of sequentially selecting M matching switches from the N matching switches, performing the operations b) through g) continuously for each of the M matching switches, and subsequently performing the operations b) through g) continuously for each matching switch, excluding the M matching switches from the N matching switches, M being less than N.

The predetermined selection scheme in the operation a) may correspond to a scheme of classifying the N matching switches into M groups, selecting one of the M groups based on the number of the plurality of target devices, and sequentially selecting matching switches included in the selected group, M being less than N.

In another aspect, there is provided a wireless power receiver including a target resonator configured to receive power from a source resonator through magnetic coupling with the source resonator, and a control and communication unit configured to detect an amount of power received by the target resonator, and to transmit, to the wireless power transmitter, information about the amount of the power received by the target resonator, wherein an impedance of the source resonator is adjusted based on at least one of a reflected wave of the charging power, an amount of a power received by the target resonator, an amount of the charging power, and a transmission efficiency of the charging power.

5

The wireless power receiver may further comprise a rectification unit configured to generate a direct current (DC) signal by rectifying an alternating current (AC) signal of the power received by the target resonator, and a DC/DC converter configured to supply a voltage of a predetermined level to a load by adjusting a level of the DC signal.

The information about the amount of power received by the target resonator may correspond to an input voltage value and an input current value of the rectification unit, an output voltage value and an output current value of the rectification unit, or a DC/DC output voltage value and a DC/DC output current value.

In one general aspect, there is provided a power receiving method of a wireless power receiver, the method including receiving power from a wireless power transmitter through magnetic coupling, receiving a first power used for charging from the wireless power transmitter, and receiving a second power used for charging, that is generated after an impedance of the source resonator is adjusted in the wireless power transmitter.

The power receiving method may further comprise receiving a wake-up request message from the wireless power transmitter, and transmitting, to the wireless power transmitter, a response message corresponding to the wake-up request message.

The first power used for charging may be generated by adjusting a signal level of a direct current (DC) voltage to be supplied to a power amplifier of the wireless power transmitter.

The impedance of the source resonator may be adjusted based on one or more of a reflected wave of the first power used for charging, an amount of the first power used for charging, and a transmission efficiency of the first power used for charging.

The response message corresponding to the wake-up request message may comprise one or more of a product type of a corresponding target device, manufacturer information of the corresponding target device, a product model name of the corresponding target device, a battery type of the corresponding target device, a charging scheme of the corresponding target device, an impedance value of a load of the corresponding target device, information about a characteristic of a target resonator of the corresponding target device, information about a used frequency band of the corresponding target device, an amount of a power to be used for the corresponding target device, an intrinsic identifier of the corresponding target device, and product version information or standards information of the corresponding target device.

The adjusted impedance of the source resonator may correspond to a tracking impedance having a power transmission efficiency above a predetermined threshold, among a plurality of predetermined tracking impedances.

The tracking impedance having the power transmission efficiency above the predetermined threshold may be determined by performing the following operations a) through c) continuously for each of the plurality of predetermined tracking impedances,

- a) receiving the second power used for charging;
- b) receiving, from the wireless power transmitter, a command to request an input voltage value and an input current value of a target device, or a command to request a DC/DC output voltage value and a DC/DC output current value of the target device; and
- c) transmitting, to the wireless power transmitter, an input voltage value and an input current value of a rectification unit, or the DC/DC output voltage value and the DC/DC output current value.

Other features and aspects will be apparent from the following detailed description, the drawings, and the claims.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a diagram illustrating an example of a wireless power transmission and charging system.

FIG. 2A is a diagram illustrating an example of a power converter and an impedance adjusting unit illustrated in FIG. 1.

FIGS. 2B through 2H are diagrams illustrating examples of various impedance adjusting units.

FIG. 3 is a diagram illustrating an example of an operation environment of a wireless power transmission and charging system.

FIG. 4 is a diagram illustrating an example of an impedance control method.

FIG. 5 is a diagram illustrating an example of an operation of adjusting an impedance illustrated in FIG. 4.

FIG. 6 is a diagram illustrating an example of a method of selecting a tracking impedance having the highest power transmission efficiency illustrated in FIG. 5.

FIGS. 7A through 7C are diagrams illustrating examples of schemes of selecting matching switches.

FIGS. 8 through 14 are diagrams illustrating examples of various resonators.

FIG. 15 is a diagram illustrating an example of an equivalent circuit of the resonator illustrated in FIG. 8.

FIG. 16 is a diagram illustrating an electric vehicle charging system.

Throughout the drawings and the detailed description, unless otherwise described, the same drawing reference numerals should be understood to refer to the same elements, features, and structures. The relative size and depiction of these elements may be exaggerated for clarity, illustration, and convenience.

DETAILED DESCRIPTION

The following detailed description is provided to assist the reader in gaining a comprehensive understanding of the methods, apparatuses and/or systems described herein. Accordingly, various changes, modifications, and equivalents of the methods, apparatuses, and/or systems described herein may be suggested to those of ordinary skill in the art. Also, descriptions of well-known functions and constructions may be omitted for increased clarity and conciseness.

Various examples herein are directed towards wireless power transmission and reception. The source and target devices described herein may be or may be included in a terminal. For example, the terminal may include a mobile phone, a computer, a tablet, an appliance, and the like. As an example, the target device may be a terminal and the source device a charging station that may be used to wireless supply power to the terminal.

FIG. 1 illustrates an example of a wireless power transmission and charging system.

Referring to FIG. 1, the wireless power transmission and charging system includes a source device 110 and a target device 120.

In this example, the source device 110 includes an alternating current-to-direct current (AC/DC) converter 111, a power supply 112, a power detector 113, a power converter 114, a control and communication (control/communication) unit 115, an impedance adjusting unit 117, and a source resonator 116. The target device 120 includes a target resonator 121, a rectification unit 122, a DC-to-DC (DC/DC)

converter **123**, a switch unit **124**, a charging unit **125**, and a control/communication unit **126**.

The AC/DC converter **111** may generate a DC voltage by rectifying an AC voltage, for example, in a band of tens of hertz (Hz) output from a power supply **112**. The AC/DC converter **111** may output a DC voltage of a predetermined level, or may adjust an output level of a DC voltage based on the control of the control/communication unit **115**.

The power detector **113** may detect an output current and an output voltage of the AC/DC converter **111**. The power detector **113** may transfer, to the control/communication unit **115**, information about the detected current and the detected voltage. Additionally, the power detector **113** may detect an input current and an input voltage of the power converter **114**.

The power converter **114** may generate a power by converting a DC voltage of a predetermined level to an AC voltage, for example, using a switching pulse signal in a band of a few megahertz (MHz) to tens of MHz. In other words, the power converter **114** may generate a communication power to be used for communication or a charging power to be used for charging in a plurality of target devices, by converting a DC voltage supplied to a power amplifier to an AC voltage using a reference resonance frequency F_{Ref} . Examples of the communication power and the charging power are described with reference to FIG. 4.

In various examples herein, the reference resonance frequency may refer to a resonance frequency used by the source device **110**. Also, the tracking frequency may refer to a resonance frequency adjusted based on a predetermined scheme.

The impedance adjusting unit **117** may include N matching switches that are connected to a plurality of capacitors. For example, the impedance adjusting unit **117** may adjust an impedance of the source resonator by controlling the N matching switches to be powered ON and OFF. For example, the impedance adjusting unit **117** may include a Pi-matching circuit or a T-matching circuit. An example of the impedance adjusting unit **117** is illustrated in FIG. 2.

The control/communication unit **115** may detect a reflected wave of the communication power or a reflected wave of the charging power, and may detect mismatching that occurs between the target resonator **121** and the source resonator **116** based on the detected reflected wave. The control/communication unit **115** may detect the mismatching by detecting an envelope of the reflected wave, or by detecting an amount of a power of the reflected wave.

The control/communication unit **115** may determine the impedance of the source resonator, and a signal level of a DC voltage that is to be supplied to the power amplifier, based on a number of a plurality of target devices. For example, the control/communication unit **115** may control the N matching switches to be powered ON and OFF, based on a reflected wave of the charging power, an amount of a power received by each of the plurality of target devices, an amount of the charging power, a transmission efficiency of the charging power, and the like.

The control/communication unit **115** may calculate a voltage standing wave ratio (VSWR), based on a voltage level of the reflected wave and a level of an output voltage of the source resonator **116** or the power converter **114**. In this example, if the VSWR is less than a predetermined value, the control/communication unit **115** may determine that a mismatch is detected. In this example, the control/communication unit **115** may control the N matching switches to be powered ON and OFF, determine a tracking impedance Im_{Best} that has the highest power transmission efficiency, and change the impedance of the source resonator to the tracking impedance Im_{Best} . It should be appreciated, however, that

Im_{Best} is merely for purposes of example. For example, the control/communication unit **115** may determine a tracking impedance that has a power transmission efficiency above a predetermined threshold.

The control/communication unit **115** may control a frequency of a switching pulse signal. Under the control of the control/communication unit **115**, the frequency of the switching pulse signal may be determined. For example, by controlling the power converter **114**, the control/communication unit **115** may generate a modulation signal that is to be transmitted to the target device **120**. In other words, the control/communication unit **115** may transmit various messages to the target device **120** via in-band communication. Additionally, the control/communication unit **115** may detect a reflected wave, and may demodulate a signal received from the target device **120** through an envelope of the reflected wave.

The control/communication unit **115** may generate a modulation signal for in-band communication, using various schemes. For example, the control/communication unit **115** may turn on or off a switching pulse signal, may perform delta-sigma modulation, and the like, to generate a modulation signal. Additionally, the control/communication unit **115** may generate a pulse-width modulation (PWM) signal with a predetermined envelope.

The control/communication unit **115** may perform out-band communication using a communication channel. For example, control/communication unit **115** may include a communication module, such as a ZigBee module, a BLUE-TOOTH® module, and the like. The control/communication unit **115** may transmit or receive data to or from the target device **120** via the out-band communication.

The source resonator **116** may transfer electromagnetic energy to the target resonator **121**. For example, the source resonator **116** may transfer the communication power or the charging power through magnetic coupling with the target resonator **121**.

Likewise, the target resonator **121** may receive the electromagnetic energy from the source resonator **116**. For example, the target resonator **121** may receive the communication power or the charging power through magnetic coupling with the source resonator **116**. Additionally, the target resonator **121** may receive various messages from the source device **110** via the in-band communication.

The rectification unit **122** may generate a DC voltage by rectifying an AC voltage. For example, the rectification unit **122** may rectify an AC voltage received by the target resonator **121**.

The DC/DC converter **123** may adjust a level of the DC voltage that is output from the rectification unit **122**, based on a capacity of the charging unit **125**. For example, the DC/DC converter **123** may adjust the level of the DC voltage output from the rectification unit **122** from about 3 volts to about 10 volts.

The switch unit **124** may be turned on or off, under the control of the control/communication unit **126**. While the switch, unit **124** is turned off, the control/communication unit **115** of the source device **110** may detect a reflected wave. In other words, while the switch unit **124** is turned off, the magnetic coupling between the source resonator **116** and the target resonator **121** may be prevented.

For example, the charging unit **125** may include a battery. The charging unit **125** may charge the battery using a DC voltage output from the DC/DC converter **123**.

The control/communication unit **126** may perform in-band communication for transmitting and/or receiving data using a resonance frequency. In this example, the control/communication unit **126** may demodulate a received signal by detect-

ing a signal between the target resonator **121** and the rectification unit **122**, or by detecting an output signal of the rectification unit **122**. In other words, the control/communication unit **126** may demodulate a message received via the in-band communication.

Additionally, the control/communication unit **126** may adjust an impedance of the target resonator **121**, in order to modulate a signal to be transmitted to the source device **110**. For example, the control/communication unit **126** may modulate the signal to be transmitted to the source device **110**, by turning on or off the switch unit **124**. In this example, the control/communication unit **126** may increase the impedance of the target resonator **121** such that a reflected wave may be detected by the control/communication unit **115** of the source device **110**. In this example, based on whether the reflected wave is detected, the control/communication unit **115** of the source device **110** may detect a binary number "0" or "1".

The control/communication unit **126** may transmit information to the wireless power transmitter. For example, the control/communication unit **126** may transmit a response message including one or more of a product type of a corresponding target device, manufacturer information of the corresponding target device, a product model name of the corresponding target device, a electric vehicle battery type, a product model name of the electric vehicle, manufacturer information of the electric vehicle, a battery type of the corresponding target device, a charging scheme of the corresponding target device and the electric vehicle, an impedance value of a load of the corresponding target device and the electric vehicle, information about a characteristic of a target resonator of the corresponding target device and the electric vehicle, information about a used frequency band of the corresponding target device and the electric vehicle, an amount of a power to be used for the corresponding target device and the electric vehicle, an intrinsic identifier of the corresponding target device, product version information or standards information of the corresponding target device and the electric vehicle, and the like.

The control/communication unit **126** may also perform an out-band communication using a communication channel. For example, the control/communication unit **126** may include a communication module, such as a ZigBee module, a BLUETOOTH® module, and the like. The control/communication unit **126** may transmit or receive data to or from the source device **110** via the out-band communication.

The control/communication unit **126** may receive a wake-up request message from the wireless power transmitter, detect an amount of a power received by the target resonator, and transmit, to the wireless power transmitter, information about the amount of the power received by the target resonator. For example, the information about the amount of the power received by the target resonator may include an input voltage value and an input current value of the rectification unit **122**, an output voltage value and an output current value of the rectification unit **122**, an output voltage value and an output current value of the DC/DC converter **123**, and the like.

The control/communication unit **115** may set a resonance bandwidth of the source resonator **116**. Based on the set resonance bandwidth of the source resonator **116**, a Q-factor (Q_s) of the source **116** may be determined.

Likewise, the control/communication unit **126** may set a resonance bandwidth of the target resonator **121**. Based on the set resonance bandwidth of the target resonator **121**, a Q-factor of the target resonator **121** may be determined. For example, the resonance bandwidth of the source resonator **116** may be set wider or narrower than the resonance band-

width of the target resonator **121**. Via a communication, the source device **110** and the target device **120** may share information about the resonance bandwidths of the source resonator **116** and the target resonator **121**. For example, if a power higher than a reference value is requested from the target device **120**, the Q-factor (Q_s) of the source resonator **116** may be set to a value greater than 100. As another example, if a power lower than the reference value is requested from the target device **120**, the Q-factor (Q_s) of the source resonator **116** may be set to a value less than 100.

Q_t indicates a Q-factor based on a change in a distance between the source resonator **116** and the target resonator **121**. In this example, a change in a resonance impedance, impedance-mismatching, a reflected signal, and the like, Q_t may be in inverse proportion to a resonance bandwidth, as given in Equation 1.

$$\begin{aligned} \frac{\Delta f}{f_0} &= \frac{1}{Q_t} \\ &= \Gamma_{s,D} + \frac{1}{BW_s} + \frac{1}{BW_D} \end{aligned} \quad [\text{Equation 1}]$$

In Equation 1, f_0 denotes a center frequency, Δf denotes a bandwidth, $\Gamma_{s,D}$ denotes reflection loss between resonators, BW_s denotes a resonance bandwidth of the source resonator **116**, and BW_D denotes a resonance bandwidth of the target resonator **121**.

In a wireless power transmission, an efficiency U of the wireless power transmission may be represented by Equation 2.

$$U = \frac{\kappa}{\sqrt{\Gamma_s \Gamma_D}} = \frac{\omega_0 M}{\sqrt{R_s R_D}} = \frac{\sqrt{Q_s Q_D}}{Q_K} \quad [\text{Equation 2}]$$

In Equation 2, κ denotes a coupling coefficient about energy coupling between the source resonator **116** and the target resonator **121**, Γ_s denotes a reflection coefficient of the source resonator **116**, Γ_D denotes a reflection coefficient of the target resonator **121**, ω_0 denotes a resonance frequency, M denotes a mutual inductance between the source resonator **116** and the target resonator **121**, R_s denotes an impedance of the source resonator **116**, R_D denotes an impedance of the target resonator **121**, Q_s denotes a Q-factor of the source resonator **116**, Q_D denotes a Q-factor of the target resonator **121**, and Q_K denotes a Q-factor about energy coupling between the source resonator **116** and the target resonator **121**.

Referring to Equation 2, the Q-factor may be associated with an efficiency of the wireless power transmission.

Accordingly, the Q-factor may be set to a greater value in order to increase the efficiency of the wireless power transmission. In this example, if Q_s and Q_D are set to a greater value, the efficiency of the wireless power transmission may be reduced based on, for example, a change in the coupling coefficient κ regarding the energy coupling, a change in a distance between the source resonator **116** and the target resonator **121**, a change in a resonance impedance, impedance mismatching, and the like.

Resonance bandwidths may be set narrow to increase efficiency of a wireless power transmission. If each of the resonance bandwidths of the source resonator **116** and the target resonator **121** is set to be too narrow, the impedance mismatching and the like may easily occur due to insignificant

11

external influences. In consideration of the impedance mismatching, Equation 1 may be expressed by Equation 3.

$$\frac{\Delta f}{f_0} = \frac{\sqrt{VSWR} - 1}{Qr\sqrt{VSWR}} \quad [\text{Equation 3}]$$

If the resonance bandwidth between the source resonator 116 and the target resonator 121, or a bandwidth of an impedance-matching frequency remains unbalanced, the efficiency of the wireless power transmission may be reduced based on, for example, a change in the coupling coefficient K, a change in a distance between the source resonator 116 and the target resonator 121, a change in a resonance impedance, impedance mismatching, and the like. According to Equation 1 through Equation 3, if the resonance bandwidth between the source resonator 116 and the target resonator 121, or the bandwidth of impedance-matching frequency remains unbalanced, the Q-factor of the source resonator 116 and the Q-factor of the target resonator 121 may remain unbalanced.

FIG. 2A illustrates an example of the power converter 114 and the impedance adjusting unit 117 which are illustrated in FIG. 1.

Referring to FIG. 2A, the power converter 114 includes a switching pulse signal generator 210 and a power amplifier 220. The impedance adjusting unit 117 includes N matching switches that are connected to a plurality of capacitors, for example, matching switches 231, 233, 235, and 237. Each of the N matching switches may be powered ON and OFF based on a control signal that is input by the control/communication unit 115. In this example, N may be an integer that is greater than 2. As an example, the matching switch 237 may be constantly in an ON state, and only one of the other matching switches 231, 233, and 235 may be in an ON state. For example, the matching switch 237 and the matching switch 235 may be simultaneously powered ON. The plurality of capacitors connected to each of the matching switches 231, 233, 235, and 237 may have different capacitance values. For example, the plurality of capacitors may be arranged in an order, starting from a capacitor having the greatest capacitance value. In this example, a capacitance value of a capacitor connected to the matching switch 233 may be greater than a capacitance value of a capacitor connect to the matching switch 231.

The switching pulse signal generator 210 may generate a switching pulse signal, for example, in a band of a few MHz to tens of MHz. A frequency of the generated switching pulse signal may be determined based on the control of the control/communication unit 115. For example, if a reference resonance frequency of the source resonator 116 corresponds to 13.56 MHz or 5.78 MHz, the control/communication unit 115 may control the switching pulse signal generator 210 to generate a switching pulse signal that has a frequency of 13.56 MHz or 5.78 MHz. The switching pulse signal generator 210 may include a plurality of capacitors, and a switch. In this example, the switching pulse signal generator 210 may adjust the frequency of the switching pulse signal by switching the plurality of capacitors.

The power amplifier 220 may generate an AC power using a switching pulse signal that is output from a resonance frequency generator. That is, the power amplifier 220 may generate a communication power used for communication and/or a charging power used for charging, by switching an input voltage of the power amplifier 220 based on the switching pulse signal.

12

The control/communication unit 115 may adjust a signal level of the input voltage of the power amplifier 220 based on a number of the plurality of target devices. Further, the control/communication unit 115 may control the N matching switches to be powered ON and OFF based on, for example, a reflected wave of charging power, an amount of a power received by each of the plurality of target devices, an amount of the charging power, a transmission efficiency of the charging power, and the like.

FIGS. 2B through 2H illustrate various impedance adjusting units.

As illustrated in the examples of FIGS. 2B through 2H, N matching switches may be connected to a plurality of capacitors or a plurality of inductors. Referring to FIGS. 2B through 2D, one of the matching switches connected to inductors may be powered ON, and simultaneously one of the matching switches connected to capacitors may be powered ON. Accordingly, for example, the impedance adjusting unit 117 illustrated in FIGS. 2B through 2D may be operated in a pi-type circuit. Referring to FIGS. 2E and 2F, N matching switches may be connected to a plurality of inductors. Referring to FIGS. 2G and 2H, the impedance adjusting unit 117 may include inductors that are connected to both ends of a capacitor in parallel.

FIG. 3 illustrates an example of an operation environment of a wireless power transmission and charging system.

Referring to FIG. 3, a source device 310 may wirelessly transmit energy to a plurality of target devices 321, 323, and 325. That is, according to a resonance-based wireless power transmission scheme, the single source device 310 may simultaneously charge the plurality of target devices 321, 323, and 325.

According to the resonance-based wireless power transmission scheme, for example, the source device 310 and the plurality of target devices 321, 323, and 325 may transmit and receive data via an in-band communication, or an out-band communication.

In an in-band communication scheme, power and a signal may be transmitted within a coupling area between a source resonator and a target resonator. In contrast to an out-band communication scheme, the in-band communication scheme may cause a little interference in peripheral devices. For example, the out-band communication may refer to a communication using a communication channel, such as a ZigBee channel, a BLUETOOTH® channel, and the like. In the in-band communication, data may be transmitted using a power transmitting channel.

FIG. 4 illustrates an example of an impedance control method.

In the example illustrated in FIG. 4, a source device, a target device 1, and a target device 2 may transmit and receive data via an in-band communication. Also, the source device, the target device 1, and the target device 2 may transmit and receive data via an out-band communication.

Referring to FIG. 4, in 410, the source device is operated in a standby mode while a target is not detected. If the target device 1 and the target device 2 are detected while in the standby mode, the source device may generate communication power to be used in the target device. That is, the source device may generate the communication power to be used by a plurality of target devices, by converting a DC voltage to be supplied to the power amplifier 220 of FIG. 2 to an AC voltage using a reference resonance frequency. In this example, the source device may transmit a test signal at each predetermined period, or may detect the target device 1 or the target device 2 using a pressure sensor. For example, if the target device 1 is disposed on the source device, the source device

13

may detect the target device **1** using the pressure sensor included in the source device. The source device may be switched from the standby mode to an access mode by a predetermined control signal. In the access mode, operations in **420** and **430** of FIG. **4** may be performed.

In **420**, the source device transmits communication power to the target device **1** and/or the target device **2** through magnetic coupling. That is, the source device may transmit communication power to the plurality of target devices using the magnetic coupling. The source device may generate the communication power used in the target device, by converting a DC voltage to be supplied to the power amplifier **220** to an AC voltage using a resonance frequency. In this example, communication power may refer to energy used for activating a communication module and a processor of each of the target devices. The communication power may be transmitted at a predetermined time in the form of a constant wave (CW). The target device **1** and the target device **2** may receive power for operating their respective communication modules and processors, by receiving the communication power.

In **430**, the source device wakes up the target device. In **430**, for example, the target device may receive a wake-up request message from the source device, and may be assigned a virtual identifier. That is, in **430**, the target device **1** and the target device **2** may activate a communication and control function by receiving the wake-up request message, and may each be assigned a virtual identifier from the source device.

Operation **430** includes operation **431** in which the source device transmits a wake-up request message to the target device **1** and the target device **2**. In **433**, the source device receives an acknowledge (ACK) message from the target device **1**, and in **435** the source device receives an ACK message from the target device **2**. For example, in **431**, the source device may transmit a wake-up request message to a plurality of target devices. In **433** and **435**, the source device may receive response messages corresponding to the wake-up request message from each of the plurality of target devices. The source device may detect the number of target devices based on the received response messages. In this example, a response message and an ACK message may refer to the same message.

For example, the ACK messages may include identifier information of each of the target device **1** and the target device **2**. The identifier information included in the ACK message may correspond to an intrinsic identifier of each of the target device **1** and the target device **2**. Each of the response messages corresponding to the wake-up request message may include, for example, one or more of a product type of a corresponding target device, manufacturer information of the corresponding target device, a product model name of the corresponding target device, a battery type of the corresponding target device, a charging scheme of the corresponding target device, an impedance value of a load of the corresponding target device, information about a characteristic of a target resonator of the corresponding target device, information about a used frequency band of the corresponding target device, an amount of a power to be used for the corresponding target device, an intrinsic identifier of the corresponding target device, product version information or standards information of the corresponding target device, and the like.

Operation **430** further includes operation **437** in which a virtual identifier is assigned to each of the target devices. The virtual identifier may be used instead of the intrinsic identifier of each of the target device **1** and the target device **2**. The virtual identifier may correspond to a temporary identifier that may be used for charging. For example, the virtual identifier may be assigned using numbers from 1 to 8 based on a

14

sequence of access. In contrast to the intrinsic identifier, the virtual identifier may be simply used for classifying the target device in **440** through **460**. In various examples, the intrinsic identifier may correspond to long data of a byte scale, including a product model name, a serial number of product, manufacturer information, and the like, whereas the virtual identifier may correspond to short data corresponding to 3 to 4 bits.

In **440**, the source device generates a charging power, and transmits the charging power to the plurality of target devices through magnetic coupling. In other words, in **440**, the source device may generate the charging power by adjusting a signal level of the DC voltage to be supplied to the power amplifier **220** based on the number of the plurality of target devices.

Also, in **440**, the source device may determine an impedance of a source resonator based on the number of target devices. In this example, the determined impedance of the source resonator may be referred to as a reference impedance. The reference impedance may be determined based on a number target devices, and/or an impedance value of a load of each of the plurality of target devices. For example, if the number of target devices is set to at least 3, the reference impedance may be determined to be greater than 50 ohms (Ω). Also, the reference impedance may be determined as a value obtained by connecting impedance values of loads of target devices in parallel.

The source device may change the impedance of the source resonator to the reference impedance, by controlling each of the N matching switches to be powered ON and/or OFF. In **440**, the source device may transmit the charging power to the target device **1** and the target device **2**. As described herein, the DC voltage to be supplied to the power amplifier **220** may refer to the input voltage of the power amplifier **220** of FIG. **2A**. The charging power may be constantly transmitted during a predetermined time, and may be transmitted at a higher power level in comparison to the communication power. For example, a power level of the communication power may correspond to 0.1 to 1 Watt, whereas a power level of the charging power may be 1 to 20 Watt.

In **440**, the control/communication unit **115** of the source device may determine a signal level of the DC voltage to be input to the power amplifier **220**, based on, for example, one or more of the product type of the corresponding target device, the manufacturer information of the corresponding target device, the product model name of the corresponding target device, the battery type of the corresponding target device, the charging scheme of the corresponding target device, the impedance value of the load of the corresponding target device, the information about the characteristic of the target resonator of the corresponding target device, the information about the used frequency band of the corresponding target device, the amount of the power to be used for the corresponding target device, and the like.

For example, the source device may determine the level of the DC voltage that is input to the power amplifier **220** to be a predetermined value, based on a battery type of the target device **1** and a battery type of the target device **2**. In this example, the source device may refer to a look-up table mapped to information of a target device, and may determine the level of the DC voltage that is input to the power amplifier **220** to be the predetermined value based on data included in the look-up table.

In **450**, the source device adjusts the impedance of the source resonator, based on a reflected wave of the charging power and a transmission efficiency of the charging power. Operation **450** performed by the source device may include operations **551** through **555** as illustrated in the example of FIG. **5**.

15

In **460**, the source device transmits a charging power used for charging. In FIG. 4, although the operations **440** through **460** are separately illustrated, the charging power may be transmitted constantly, without discontinuity. That is, the charging power may be constantly transmitted while the impedance of the source resonator is adjusted. However, because the charging power transmitted in **460** may be a power transmitted after an impedance-matching is completed, the charging power transmitted in **460** may have a better power transmission efficiency in comparison to the charging power transmitted in **440**.

In FIG. 4, the charging power in **440** is referred to as a first charging power, and the charging power in **460** is referred to as a second charging power. Accordingly, a wireless power receiver may receive the first charging power from a wireless power transmitter, and receive the second charging power generated after the impedance of the source resonator is adjusted, in the wireless power transmitter. For example, the impedance of the source resonator may be adjusted based on a reflected wave of the first charging power, an amount of the first charging power, a transmission efficiency of the first charging power, and the like.

In **450**, the wireless power receiver may continuously perform a) receiving the second charging power, b) receiving, from the wireless power transmitter, a request for an input voltage value and an input current value of a target device, or a request for a DC/DC output voltage value and a DC/DC output current value of the target device, and c) transmitting, to the wireless power transmitter, the requested input voltage value and input current value of a rectification unit, or the requested DC/DC output voltage value and the DC/DC output current value.

FIG. 5 illustrates an example of an operation of adjusting impedance.

Referring to FIG. 5, in **551**, a source device calculates a voltage standing wave ratio (VSWR) based on a voltage level of a reflected wave, and a level of an output voltage and a level of an output current of the source resonator.

In **553**, the source device determines whether the calculated VSWR is less than a predetermined value. For example, if the VSWR is less than the predetermined value, the source device may control N matching switches to be powered ON and OFF, and may determine a tracking impedance Im_{Best} that has the highest power transmission efficiency, in **555**. In this example, the tracking impedance Im_{Best} may be determined by performing operations **610** through **660** of FIG. 6 continuously for each of the N matching switches. After performing the operation in **555**, the source device may change the impedance of the source resonator to the tracking impedance Im_{Best} .

FIG. 6 illustrates an example of a method of selecting the tracking impedance Im_{Best} that has the highest power transmission efficiency.

For example, operations **610** through **660** of FIG. 6 may be performed by the control/communication unit **115** of FIG. 1 or FIG. 2A.

Referring to FIG. 6, in **610**, a source device selects one of N matching switches based on a predetermined selection scheme. For example, the predetermined selection method may be one of schemes illustrated in FIGS. 7A through 7C.

In **620**, the source device changes an impedance of a source resonator to a selected impedance $Im_{Selected}$ by controlling the selected matching switch to be powered ON.

In **630**, the source device transmits a charging power to be used for charging. For example, the charging power transmit-

16

ted in **630** may correspond to a power transmitted when the impedance of the source resonator corresponds to the selected impedance $Im_{Selected}$.

In **640**, the source device requests information from target devices. That is, the source device may transmit, to the plurality of target devices, a command requesting an input voltage value and an input current value of a target device, or a command requesting a DC/DC output voltage value and a DC/DC output current value of the target device.

In **641** and **643**, the source device receives, from each of the plurality of target devices, the requested input voltage value and an input current value of a rectification unit, or the requested DC/DC output voltage value and the DC/DC output current value.

In **650**, the source device calculates an amount of a power received by each of the plurality of target devices, based on the input voltage value and the input current value, or the DC/DC output voltage value and the DC/DC output current value.

In **660**, the source device calculates a transmission efficiency of the charging power, based on a level of an output voltage and a level of an output current of a source resonator, and the amount of the power received by each of the plurality of target devices. For example, the level of the output voltage and the output current of the source resonator may correspond to a level of the input voltage of the power amplifier **220** illustrated in FIG. 2A, and a level of a current flowing into the power amplifier **200**. As another example, the level of the output voltage and the output current of the source resonator may correspond to a level of an output voltage and a level of an output current of the power converter **114** of FIG. 1. The power transmission efficiency may be calculated based on a summation of the amounts of power received by each of the target devices, and a ratio of a level of an output power of the source resonator. The level of the output power of the source resonator may correspond to a value that is obtained by multiplying a level of an output voltage and a level of an output current of the source resonator.

FIGS. 7A through 7C illustrate examples of schemes of selecting matching switches.

FIG. 7A illustrates a scheme of selecting matching switches such that a plurality of capacitors may be powered ON and OFF in a sequential order, starting from a capacitor having a low capacitance value to a capacitor having a high capacitance value.

FIG. 7B illustrates a scheme of selecting matching switches such that a plurality of capacitors may be powered ON and OFF in a sequential order, starting from a capacitor having a high capacitance value to a capacitor having a low capacitance value.

FIG. 7C illustrates a scheme of sequentially selecting M predetermined matching switches from among N matching switches, for performing the operations **620** through **660** continuously for each of the M matching switches, and for secondarily performing the operations **620** through **660** continuously for each matching switch, excluding the M matching switches from the N matching switches. In this example, M may be less than N. That is, in the scheme of FIG. 7C, a source device may select SW3 and SW8, and may perform the operations **620** through **660** continuously for SW3 and SW8. Then, the source device may perform the operations **620** through **660** continuously for SW1, SW2, SW4, SW5, SW6, SW7, SW9, SW10, and SW11 through SWN, excluding SW3 and SW8.

The source device may employ a scheme of classifying N matching switches into M groups, for example, a first group **710** and a second group **720**, selecting one of the M groups

based on a number of target devices, and sequentially selecting matching switches included in the selected group. For example, if a number of target devices is set to less than 4, the source device may select the first group 710, and may perform operations 620 through 660 continuously for SW1, SW2, SW3, SW4, and SW5 included in the first group 710.

In a wireless power transmission and charging system, a loss of transmission power may be reduced by controlling a resonance frequency, without a separate matching circuit.

In a wireless power transmission and charging system, a resonance frequency may be controlled based on a power transmission efficiency.

In various examples, a source resonator, a repeater resonator, and/or a target resonator may be configured as a helix coil structured resonator, a spiral coil structured resonator, a meta-structured resonator, or the like.

FIG. 8 is an example of a two-dimensional (2D) illustration of a resonator.

Referring to FIG. 8, resonator 800 includes a transmission line, a capacitor 820, a matcher 830, and conductors 841 and 842. The transmission line includes a first signal conducting portion 811, a second signal conducting portion 812, and a ground conducting portion 813.

The capacitor 820 may be inserted in series between the first signal conducting portion 811 and the second signal conducting portion 812, and an electric field may be confined within the capacitor 820. The transmission line may include at least one conductor in an upper portion of the transmission line, and at least one conductor in a lower portion of the transmission line. Current may flow through the at least one conductor disposed in the upper portion of the transmission line and the at least one conductor disposed in the lower portion of the transmission line may be electrically grounded. A conductor disposed in an upper portion of the transmission line may be referred to as the first signal conducting portion 811 and the second signal conducting portion 812. A conductor disposed in the lower portion of the transmission line may be referred to as the ground conducting portion 813.

The transmission line may include the first signal conducting portion 811 and the second signal conducting portion 812 in the upper portion of the transmission line, and may include the ground conducting portion 813 in the lower portion of the transmission line. The first signal conducting portion 811 and the second signal conducting portion 812 may face the ground conducting portion 813. For example, current may flow through the first signal conducting portion 811 and the second signal conducting portion 812.

In this example, one end of the first signal conducting portion 811 is shorted to a conductor 842, and another end of the first signal conducting portion 811 is connected to the capacitor 820. One end of the second signal conducting portion 812 is shorted to the conductor 841, and another end of the second signal conducting portion 812 is connected to the capacitor 820. Accordingly, the first signal conducting portion 811, the second signal conducting portion 812, the ground conducting portion 813, and the conductors 841 and 842 are connected to each other such that the resonator 800 may have an electrically closed-loop structure. The term "loop structure" may include a polygonal structure, for example, a circular structure, a rectangular structure, and the like. "Having a loop structure" indicates a circuit that is electrically closed.

The capacitor 820 may be inserted into an intermediate portion of the transmission line. For example, the capacitor 820 may be inserted into a space between the first signal conducting portion 811 and the second signal conducting portion 812. The capacitor 820 may have a shape of a lumped

element, a distributed element, and the like. As an example, a distributed capacitor having the shape of the distributed element may include zigzagged conductor lines and a dielectric material having a relatively high permittivity and that is located between the zigzagged conductor lines.

If the capacitor 820 is inserted into the transmission line, the resonator 800 may have a property of a metamaterial. A metamaterial indicates a material that has an electrical property that has not been discovered in nature and thus, may have an artificially designed structure. An electromagnetic characteristic of all the materials existing in nature have a unique magnetic permeability or a unique permittivity. Most materials have a positive magnetic permeability or a positive permittivity. In the case of most materials, a right hand rule may be applied to an electric field, a magnetic field, and a pointing vector, and thus, the corresponding materials may be referred to as right handed materials (RHMs). However, a metamaterial has a magnetic permeability or a permittivity that is absent in nature, and thus, may be classified into, for example, an epsilon negative (ENG) material, a mu negative (MNG) material, a double negative (DNG) material, a negative refractive index (NRI) material, a left-handed (LH) material, and the like, based on a sign of the corresponding permittivity or magnetic permeability.

The resonator 800 may have a negative magnetic permeability by appropriately adjusting the capacitance of the capacitor 820. In this example, the resonator 800 may also be referred to as an MNG resonator. Various criteria may be applied to determine the capacitance of the capacitor 820. For example, the various criteria may include a criterion for enabling the resonator 800 to have the characteristic of the metamaterial, a criterion for enabling the resonator 800 to have a negative magnetic permeability in a target frequency, a criterion for enabling the resonator 800 to have a zeroth order resonance characteristic in the target frequency, and the like. Based on at least one criterion from among the aforementioned criteria, the capacitance of the capacitor 820 may be determined.

The resonator 800, also referred to as the MNG resonator 800, may have a zeroth order resonance characteristic of having, as a resonance frequency, a frequency in which a propagation constant is "0". Because the resonator 800 may have the zeroth order resonance characteristic, the resonance frequency may be independent with respect to a physical size of the MNG resonator 800. By appropriately designing the capacitor 820, the MNG resonator 800 may sufficiently change the resonance frequency. Accordingly, the physical size of the MNG resonator 800 may not be changed.

In a near field, the electric field may be concentrated on the capacitor 820 inserted into the transmission line. In this example, due to the capacitor 820, the magnetic field may become dominant in the near field. The MNG resonator 800 may have a relatively high Q-factor using the capacitor 820 of the lumped element, and thus, it is possible to enhance an efficiency of power transmission. A Q-factor indicates a level of an ohmic loss or a ratio of a reactance with respect to a resistance in the wireless power transmission. The efficiency of the wireless power transmission may increase according to an increase in the Q-factor.

The matcher 830 may adjust a strength of a magnetic field of the MNG resonator 800. Accordingly, an impedance of the MNG resonator 800 may be determined by the matcher 830. Current may flow in the MNG resonator 800 via a connector, or may flow out from the MNG resonator 800 via the connector. The connector may be connected to the ground conducting portion 813 or the matcher 830. For example, a physical connection may be formed between the connector and the

19

ground conducting portion **813**, or between the connector and the matcher **830**. As another example, power may be transferred through coupling, without using a physical connection between the connector and the ground conducting portion **813** or the matcher **830**.

For example, as shown in FIG. **8**, the matcher **830** may be positioned within the loop formed by the loop structure of the resonator **800**. The matcher **830** may adjust the impedance of the resonator **800** by changing the physical shape of the matcher **830**. For example, the matcher **830** includes the conductor **831** for the impedance-matching in a location that is separated from the ground conducting portion **813** by a distance *h*. In this example, the impedance of the resonator **800** may be changed by adjusting the distance *h*.

Although not illustrated in FIG. **8**, a controller may be provided to control the matcher **830**. In this example, the matcher **830** may change the physical shape of the matcher **830** based on a control signal generated by the controller. For example, the distance *h* between a conductor **831** of the matcher **830** and the ground conducting portion **813** may increase or decrease based on the control signal. Accordingly, the physical shape of the matcher **830** may be changed and the impedance of the resonator **800** may be adjusted.

As shown in FIG. **8**, the matcher **830** may be configured as a passive element such as the conductor **831**. For example, the matcher **830** may be an active element such as a diode, a transistor, and the like. If the active element is included in the matcher **830**, the active element may be driven based on the control signal generated by the controller, and the impedance of the resonator **800** may be adjusted based on the control signal. In an example in which a diode is included in the matcher **830**, the impedance of the resonator **800** may be adjusted based on whether the diode is in an on state or in an off state.

Although not illustrated in FIG. **8**, a magnetic core may pass through the MNG resonator **800**. The magnetic core may increase a power transmission distance.

FIG. **9** is an example of a three-dimensional (3D) illustration of a resonator.

Referring to FIG. **9**, resonator **900** includes a transmission line and a capacitor **920**. The transmission line includes a first signal conducting portion **911**, a second signal conducting portion **912**, and a ground conducting portion **913**. The capacitor **920** is inserted in series between the first signal conducting portion **911** and the second signal conducting portion **912** of the transmission line, and an electric field may be confined within the capacitor **920**.

The transmission line includes the first signal conducting portion **911** and the second signal conducting portion **912** in an upper portion of the resonator **900**, and includes the ground conducting portion **913** in a lower portion of the resonator **900**. In this example, the first signal conducting portion **911** and the second signal conducting portion **912** face the ground conducting portion **913**. Current may flow in an *x* direction through the first signal conducting portion **911** and the second signal conducting portion **912**. Due to the current, a magnetic field *H*(*W*) may be formed in a *-y* direction. Alternatively, unlike the diagram of FIG. **9**, the magnetic field *H*(*W*) may be formed in a *+y* direction.

One end of the first signal conducting portion **911** is shorted to a conductor **942**, and another end of the first signal conducting portion **911** is connected to the capacitor **920**. One end of the second signal conducting portion **912** is shorted to the conductor **941**, and another end of the second signal conducting portion **912** is connected to the capacitor **920**. Accordingly, the first signal conducting portion **911**, the second signal conducting portion **912**, the ground conducting

20

portion **913**, and the conductors **941** and **942** are connected to each other such that the resonator **900** has an electrically closed-loop structure.

As shown in FIG. **9**, the capacitor **920** may be inserted into a space between the first signal conducting portion **911** and the second signal conducting portion **912**. For example, the capacitor **920** may have a shape of a lumped element, a distributed element, and the like. As an example, a distributed capacitor having the shape of the distributed element may include zigzagged conductor lines and a dielectric material having a relatively high permittivity that is disposed between the zigzagged conductor lines.

As the capacitor **920** is inserted into the transmission line, the resonator **900** may have a property of a metamaterial. If a capacitance of the capacitor inserted as the lumped element is appropriately determined, the resonator **900** may have the characteristic of the metamaterial. Because the resonator **900** may have a negative magnetic permeability in a predetermined frequency band by adjusting the capacitance of the capacitor **920**, the resonator **900** may also be referred to as an MNG resonator. Various criteria may be applied to determine the capacitance of the capacitor **920**. For example, the various criteria may include a criterion for enabling the resonator **900** to have the characteristic of the metamaterial, a criterion for enabling the resonator **900** to have a negative magnetic permeability in a target frequency, a criterion for enabling the resonator **900** to have a zeroth order resonance characteristic in the target frequency, and the like. Based on at least one criterion from among the aforementioned criteria, the capacitance of the capacitor **920** may be determined.

The resonator **900**, also referred to as the MNG resonator **900**, may have a zeroth order resonance characteristic of having, as a resonance frequency, a frequency in which a propagation constant is "0". Because the resonator **900** may have the zeroth order resonance characteristic, the resonance frequency may be independent with respect to a physical size of the MNG resonator **900**. By appropriately designing the capacitor **920**, the MNG resonator **900** may sufficiently change the resonance frequency. Accordingly, the physical size of the MNG resonator **900** may not be changed.

Referring to the MNG resonator **900** of FIG. **9**, in a near field, the electric field may be concentrated on the capacitor **920** inserted into the transmission line. Accordingly, due to the capacitor **920**, the magnetic field may become dominant in the near field. For example, because the MNG resonator **900** having the zeroth order resonance characteristic may have characteristics similar to a magnetic dipole, the magnetic field may become dominant in the near field. A relatively small amount of the electric field formed due to the insertion of the capacitor **920** may be concentrated on the capacitor **920**, and thus, the magnetic field may become further dominant. The MNG resonator **900** may have a relatively high Q-factor using the capacitor **920** of the lumped element, and thus, it is possible to enhance an efficiency of power transmission.

The matcher **930** may be used to adjust the strength of magnetic field of the MNG resonator **900**. An impedance of the MNG resonator **900** may be determined by the matcher **930**. Current may flow in the MNG resonator **900** via a connector **940**, or may flow out from the MNG resonator **900** via the connector **940**. As an example, the connector **940** may be connected to the ground conducting portion **913** or the matcher **930**.

For example, as shown in FIG. **9**, the matcher **930** may be positioned within the loop formed by the loop structure of the resonator **900**. The matcher **930** may adjust the impedance of the resonator **900** by changing the physical shape of the

21

matcher 930. For example, the matcher 930 includes the conductor 931 for the impedance-matching in a location that is separated from the ground conducting portion 913 by a distance h. The impedance of the resonator 900 may be changed by adjusting the distance h.

Although not illustrated in FIG. 9, a controller may be provided to control the matcher 930. In this example, the matcher 930 may change the physical shape of the matcher 930 based on a control signal generated by the controller. For example, the distance h between the conductor 931 of the matcher 930 and the ground conducting portion 913 may increase or decrease based on the control signal. Accordingly, the physical shape of the matcher 930 may be changed and the impedance of the resonator 900 may be adjusted. The distance h between the conductor 931 of the matcher 930 and the ground conducting portion 913 may be adjusted using a variety of schemes. As one example, a plurality of conductors may be included in the matcher 930 and the distance h may be adjusted by adaptively activating one of the conductors. As another example, the distance h may be adjusted by adjusting the physical location of the conductor 931 up and down. The distance h may be controlled based on the control signal of the controller. The controller may generate the control signal using various factors. An example of the controller generating the control signal is described later.

As shown in FIG. 9, the matcher 930 may be a passive element such as the conductor 931. For example, the matcher 930 may be an active element such as a diode, a transistor, and the like. If the active element is included in the matcher 930, the active element may be driven based on the control signal generated by the controller, and the impedance of the resonator 900 may be adjusted based on the control signal. For example, if a diode is included in the matcher 930, the impedance of the resonator 900 may be adjusted based on whether the diode is in an on state or in an off state.

Although not illustrated in FIG. 9, a magnetic core may pass through the resonator 900 configured as the MNG resonator. The magnetic core may increase a power transmission distance.

FIG. 10 illustrates an example of a resonator for a wireless power transmission configured as a bulky type.

Referring to FIG. 10, a first signal conducting portion 1011 and a conductor 1042 may be integrally formed of one piece instead of being separately manufactured and subsequently connected to each other. Similarly, the second signal conducting portion 1012 and a conductor 1041 may be integrally manufactured.

If the second signal conducting portion 1012 and the conductor 1041 are separately manufactured and then are connected to each other, a loss of conduction may occur due to a seam 1050. Accordingly, the second signal conducting portion 1012 and the conductor 1041 may be connected to each other without using a separate seam, that is, they may be seamlessly connected to each other. Accordingly, it is possible to decrease a conductor loss that is caused by the seam 1050. As another example, the second signal conducting portion 1012 and a ground conducting portion 1013 may be seamlessly and integrally manufactured. As another example, the first signal conducting portion 1011 and the ground conducting portion 1013 may be seamlessly and integrally manufactured. As another example, the first signal conducting portion 1011 and the conductor 1042 may be seamlessly manufactured. As another example, the conductor 1042 and the ground conducting portion 1013 may be seamlessly manufactured.

22

Referring to FIG. 10, a type of a seamless connection connecting at least two partitions into an integrated form is referred to as a bulky type.

FIG. 11 illustrates an example of a resonator for a wireless power transmission, configured as a hollow type.

Referring to FIG. 11, one or more of a first signal conducting portion 1111, a second signal conducting portion 1112, a ground conducting portion 1113, and conductors 1141 and 1142 of the resonator 1100 configured as the hollow type may include an empty or hollow space inside.

In a given resonance frequency, an active current may be modeled to flow in only a portion of the first signal conducting portion 1111 instead of the entire first signal conducting portion 1111, only a portion of the second signal conducting portion 1112 instead of the entire second signal conducting portion 1112, only a portion of the ground conducting portion 1113 instead of the entire ground conducting portion 1113, and only a portion of the conductors 1141 and 1142 instead of the entire conductors 1141 and 1142. For example, if a depth of each of the first signal conducting portion 1111, the second signal conducting portion 1112, the ground conducting portion 1113, and the conductors 1141 and 1142 are significantly deeper than a corresponding skin depth in the given resonance frequency, it may be ineffective. The significantly deeper depth may increase a weight or manufacturing costs of the resonator 1100.

Accordingly, in the given resonance frequency, the depth of each of the first signal conducting portion 1111, the second signal conducting portion 1112, the ground conducting portion 1113, and the conductors 1141 and 1142 may be determined based on the corresponding skin depth of each of the first signal conducting portion 1111, the second signal conducting portion 1112, the ground conducting portion 1113, and the conductors 1141 and 1142. If each of the first signal conducting portion 1111, the second signal conducting portion 1112, the ground conducting portion 1113, and the conductors 1141 and 1142 has an appropriate depth deeper than a corresponding skin depth, the resonator 1100 may become light, and manufacturing costs of the resonator 1100 may also decrease.

For example, as shown in FIG. 11, the depth of the second signal conducting portion 1112 may be determined as "d" mm. In this example, d may be determined according to

$$d = \frac{1}{\sqrt{\pi f \mu \sigma}}.$$

Here, f denotes a frequency, μ denotes a magnetic permeability, and σ denotes a conductor constant. As an example, if the first signal conducting portion 1111, the second signal conducting portion 1112, the ground conducting portion 1113, and the conductors 1141 and 1142 are made of a copper and have a conductivity of 5.8×10^7 Siemens per meter ($\text{S} \cdot \text{m}^{-1}$), the skin depth may be about 0.6 mm with respect to 10 kHz of the resonance frequency and the skin depth may be about 0.006 mm with respect to 100 MHz of the resonance frequency.

FIG. 12 illustrates an example of a resonator for a wireless power transmission using a parallel-sheet.

Referring to FIG. 12, the parallel-sheet may be applicable to each of a first signal conducting portion 1211 and a second signal conducting portion 1212 included in the resonator 1200.

Each of the first signal conducting portion 1211 and the second signal conducting portion 1212 may not be a perfect

23

conductor, and thus, may have some resistance. Due to the resistance, an ohmic loss may occur. The ohmic loss may decrease a Q-factor and also decrease a coupling effect.

By applying the parallel-sheet to each of the first signal conducting portion **1211** and the second signal conducting portion **1212**, it is possible to decrease the ohmic loss, and to increase the Q-factor and the coupling effect. Referring to a portion **1270** indicated by a circle, the parallel-sheet is applied, and each of the first signal conducting portion **1211** and the second signal conducting portion **1212** includes a plurality of conductor lines. The plurality of conductor lines are disposed in parallel, and are shorted at an end portion of each of the first signal conducting portion **1211** and the second signal conducting portion **1212**.

By applying the parallel-sheet example to each of the first signal conducting portion **1211** and the second signal conducting portion **1212**, the plurality of conductor lines may be disposed in parallel. Accordingly, a sum of resistances having the conductor lines may decrease. Consequently, the resistance loss may decrease, and the Q-factor and the coupling effect may increase.

FIG. **13** illustrates an example of a resonator for a wireless power transmission, including a distributed capacitor.

Referring to FIG. **13**, a capacitor **1320** included in resonator **1300** for the wireless power transmission may be a distributed capacitor. A capacitor as a lumped element may have a relatively high equivalent series resistance (ESR). A variety of schemes have been proposed to decrease the ESR contained in the capacitor of the lumped element. For example, by using the capacitor **1320** as a distributed element, it is possible to decrease the ESR. Loss caused by the ESR may decrease a Q-factor and a coupling effect.

As shown in FIG. **13**, the capacitor **1320** as the distributed element may have a zigzagged structure. For example, the capacitor **1320** as the distributed element may be configured as a conductive line and a conductor having the zigzagged structure.

By including the capacitor **1320** as the distributed element, it is possible to decrease the loss occurring due to the ESR. In addition, by disposing a plurality of capacitors as lumped elements, it is possible to decrease the loss occurring due to the ESR. Because a resistance of each of the capacitors as the lumped elements decreases through a parallel connection, active resistances of parallel-connected capacitors as the lumped elements may also decrease and the loss occurring due to the ESR may decrease. For example, by including ten capacitors of 1 pF instead of using a single capacitor of 10 pF, it is possible to decrease the loss occurring due to the ESR.

FIG. **14A** illustrates an example of the matcher **830** used in the resonator **800** provided in FIG. **8**, and FIG. **14B** illustrates an example of the matcher **930** used in the resonator **900** provided in FIG. **9**.

Specifically, FIG. **14A** illustrates a portion of the resonator **800** including the matcher **830**, and FIG. **14B** illustrates a portion of the resonator **900** including the matcher **930**.

Referring to FIG. **14A**, the matcher **830** includes a conductor **831**, a conductor **832**, and a conductor **833**. The conductors **832** and **833** are connected to the ground conducting portion **813** and the conductor **831**. The impedance of the resonator may be determined based on a distance *h* between the conductor **831** and the ground conducting portion **813**. The distance *h* between the conductor **831** and the ground conducting portion **813** may be controlled by the controller. The distance *h* between the conductor **831** and the ground conducting portion **813** may be adjusted using a variety of schemes. For example, the variety of schemes may include a scheme of adjusting the distance *h* by adaptively activating

24

one of the conductors **831**, **832**, and **833**, a scheme of adjusting the physical location of the conductor **831** up and down, and the like.

Referring to FIG. **14B**, the matcher **930** includes a conductor **931**, a conductor **932**, and a conductor **933**. The conductors **932** and **933** are connected to the ground conducting portion **913** and the conductor **931**. The impedance of the resonator may be determined based on a distance *h* between the conductor **931** and the ground conducting portion **913**. The distance *h* between the conductor **931** and the ground conducting portion **913** may be controlled by the controller. Similar to the matcher **830** included in the resonator **800**, the distance *h* between the conductor **931** and the ground conducting portion **913** may be adjusted using a variety of schemes. For example, the variety of schemes may include a scheme of adjusting the distance *h* by adaptively activating one of the conductors **931**, **932**, and **933**, a scheme of adjusting the physical location of the conductor **931** up and down, and the like.

Although not illustrated in FIGS. **14A** and **14B**, the matcher may include an active element. For example, the impedance of the resonator may be adjusted by changing a path of a current flowing through the matcher using the active element.

FIG. **15** illustrates an example of an equivalent circuit of the resonator **800** for the wireless power transmission of FIG. **8**.

The resonator **800** for the wireless power transmission may be modeled to the equivalent circuit of FIG. **15**. In the equivalent circuit of FIG. **15**, C_L denotes a capacitor that is inserted in the form of a lumped element in the middle of the transmission line of FIG. **8**.

For example, the resonator **800** may have a zeroth resonance characteristic. If a propagation constant is "0", the resonator **800** may be assumed to have ω_{MZR} as a resonance frequency. The resonance frequency ω_{MZR} may be expressed by Equation 4.

$$\omega_{MZR} = \frac{1}{\sqrt{L_R C_L}} \quad [\text{Equation 4}]$$

In Equation 4, MZR denotes a Mu zero resonator.

Referring to Equation 4, the resonance frequency ω_{MZR} of the resonator **800** may be determined by L_R/C_L . A physical size of the resonator **800** and the resonance frequency ω_{MZR} may be independent with respect to each other. Because the physical sizes are independent with respect to each other, the physical size of the resonator **800** may be sufficiently reduced.

FIG. **16** illustrates an electric vehicle charging system.

Referring to FIG. **16**, an electric vehicle charging system **1600** includes a source system **1610**, a source resonator **1620**, a target resonator **1630**, a target system **1640**, and an electric vehicle battery **1650**.

The electric vehicle charging system **1600** may have a similar structure to the wireless power transmission system of FIG. **1**. The source system **1610** and the source resonator **1620** in the electric vehicle charging system **1600** may function as a source. Additionally, the target resonator **1630** and the target system **1640** in the electric vehicle charging system **1600** may function as a target.

The source system **1610** may include a variable SMPS, a power amplifier, a matching network, a controller, and a communication unit, similarly to the source **110** of FIG. **1**. The target system **1640** may include a matching network, a

rectification unit, a DC/DC converter, a communication unit, and a controller, similarly to the target **120** of FIG. **1**.

The electric vehicle battery **1650** may be charged by the target system **1640**.

The electric vehicle charging system **1600** may use a resonant frequency in a band of a few kilohertz (KHz) to tens of MHz.

The source system **1610** may generate power, based on a type of charging vehicle, a capacity of a battery, and a charging state of a battery, and may supply the generated power to the target system **1640**.

The source system **1610** may control the source resonator **1620** and the target resonator **1630** to be aligned. For example, when the source resonator **1620** and the target resonator **1630** are not aligned, the controller of the source system **1610** may transmit a message to the target system **1640**, and may control alignment between the source resonator **1620** and the target resonator **1630**.

For example, when the target resonator **1630** is not located in a position enabling maximum magnetic resonance, the source resonator **1620** and the target resonator **1630** may not be aligned. When a vehicle does not stop accurately, the source system **1610** may induce a position of the vehicle to be adjusted, and may control the source resonator **1620** and the target resonator **1630** to be aligned.

The source system **1610** and the target system **1640** may transmit or receive an ID of a vehicle, or may exchange various messages, through communication.

The descriptions of FIGS. **2** through **15** may be applied to the electric vehicle charging system **1600**. However, the electric vehicle charging system **1600** may use a resonant frequency in a band of a few KHz to tens of MHz, and may transmit power that is equal to or higher than tens of watts to charge the electric vehicle battery **1650**.

Program instructions to perform a method described herein, or one or more operations thereof, may be recorded, stored, or fixed in one or more computer-readable storage media. The program instructions may be implemented by a computer. For example, the computer may cause a processor to execute the program instructions. The media may include, alone or in combination with the program instructions, data files, data structures, and the like. Examples of computer-readable storage media include magnetic media, such as hard disks, floppy disks, and magnetic tape; optical media such as CD ROM disks and DVDs; magneto-optical media, such as optical disks; and hardware devices that are specially configured to store and perform program instructions, such as read-only memory (ROM), random access memory (RAM), flash memory, and the like. Examples of program instructions include machine code, such as produced by a compiler, and files containing higher level code that may be executed by the computer using an interpreter. The program instructions, that is, software, may be distributed over network coupled computer systems so that the software is stored and executed in a distributed fashion. For example, the software and data may be stored by one or more computer readable storage mediums. Also, functional programs, codes, and code segments for accomplishing the example embodiments disclosed herein can be easily construed by programmers skilled in the art to which the embodiments pertain based on and using the flow diagrams and block diagrams of the figures and their corresponding descriptions as provided herein. Also, the described unit to perform an operation or a method may be hardware, software, or some combination of hardware and software. For example, the unit may be a software package running on a computer or the computer on which that software is running.

As a non-exhaustive illustration only, a terminal/device/unit described herein may refer to mobile devices such as a cellular phone, a personal digital assistant (PDA), a digital camera, a portable game console, and an MP3 player, a portable/personal multimedia player (PMP), a handheld e-book, a portable laptop PC, a global positioning system (GPS) navigation, a tablet, a sensor, and devices such as a desktop PC, a high definition television (HDTV), an optical disc player, a setup box, a home appliance, and the like that are capable of wireless communication or network communication consistent with that which is disclosed herein.

A computing system or a computer may include a microprocessor that is electrically connected with a bus, a user interface, and a memory controller. It may further include a flash memory device. The flash memory device may store N-bit data via the memory controller. The N-bit data is processed or will be processed by the microprocessor and N may be 1 or an integer greater than 1. Where the computing system or computer is a mobile apparatus, a battery may be additionally provided to supply operation voltage of the computing system or computer. It will be apparent to those of ordinary skill in the art that the computing system or computer may further include an application chipset, a camera image processor (CIS), a mobile Dynamic Random Access Memory (DRAM), and the like. The memory controller and the flash memory device may constitute a solid state drive/disk (SSD) that uses a non-volatile memory to store data.

A number of examples have been described above. Nevertheless, it will be understood that various modifications may be made. For example, suitable results may be achieved if the described techniques are performed in a different order and/or if components in a described system, architecture, device, or circuit are combined in a different manner and/or replaced or supplemented by other components or their equivalents. Accordingly, other implementations are within the scope of the following claims.

What is claimed is:

1. An impedance control method of a wireless power transmitter configured to transmit power to at least one of target device, the method comprising:
 - generating power for charging by determining an impedance of a source resonator, and adjusting a voltage level of a direct current (DC) voltage to be supplied to a power amplifier;
 - transmitting the charging power to the at least one of target device through magnetic coupling; and
 - adjusting the impedance of the source resonator based on one or more of a reflected wave of the charging power, an amount of power received by each of the at least one of target device, an amount of the charging power, or a transmission efficiency of the charging power.
2. The method of claim 1, further comprising, prior to generating a charging power:
 - transmitting a wake-up request message to the at least one of target device;
 - receiving response messages corresponding to the wake-up request message from the at least one of target device; and
 - detecting the number of the at least one of target device based on the received response messages.
3. The method of claim 2, wherein each of the response messages comprises one or more of a product type of a corresponding target device, manufacturer information of the corresponding target device, a product model name of the corresponding target device, a battery type of the corresponding target device, a charging scheme of the corresponding target device, an impedance value of a load of the correspond-

27

ing target device, information about a characteristic of a target resonator of the corresponding target device, information about a used frequency band of the corresponding target device, an amount of a power to be used for the corresponding target device, an intrinsic identifier of the corresponding target device, and product version information or standards information of the corresponding target device.

4. The method of claim 1, wherein the adjusting of the impedance of the source resonator is performed by controlling N matching switches to be powered ON and/or OFF, and the N matching switches are connected to a plurality of capacitors and/or a plurality of inductors.

5. The method of claim 4, wherein the adjusting of the impedance of the source resonator comprises:

calculating a voltage standing wave ratio (VSWR) based on a voltage level of the reflected wave, a level of an output voltage, and a level of an output current of a source resonator;

controlling the N matching switches to be powered ON and OFF, in response to the VSWR being less than a predetermined reference value;

determining a tracking impedance having a power transmission efficiency above a predetermined threshold; and changing the impedance of the source resonator to the tracking impedance having the power transmission efficiency above the predetermined threshold.

6. The method of claim 5, wherein the determining of the tracking impedance having the power transmission efficiency above a predetermined threshold comprises performing the following operations a) through g) continuously for each of the N matching switches,

a) selecting at least one of the N matching switches based on a predetermined selection scheme;

b) changing the impedance of the source resonator to a selected impedance, by controlling the at least one selected matching switch to be powered ON;

c) transmitting the charging power;

d) transmitting, to the at least one of target device, a command to request an input voltage value and an input current value of a target device, or a command to request a DC/DC output voltage value and a DC/DC output current value of the target device;

e) receiving, from each of the at least one of target device, an input voltage value and an input current value of a rectification unit, or the DC/DC output voltage value and the DC/DC output current value;

f) calculating an amount of a power received by each of the at least one of target device, based on the input voltage value and the input current value, or the DC/DC output voltage value and the DC/DC output current value; and

g) calculating a transmission efficiency of the charging power, based on an output voltage level and an output current level of the source resonator, and the amount of a power received by each of the at least one of target device.

7. The method of claim 6, wherein the predetermined selection scheme in the operation a) corresponds to a scheme of selecting matching switches so that the plurality of capacitors may be powered ON and OFF in a sequential order, beginning from a capacitor having a lowest capacitance value to a capacitor having a highest capacitance value, or a scheme of selecting matching switches so that the plurality of capacitors may be powered ON and OFF in a sequential order, beginning from the capacitor having the highest capacitance value to the capacitor having the lowest capacitance value.

8. The method of claim 7, wherein the predetermined selection scheme in the operation a) corresponds to a scheme of

28

classifying the N matching switches into M groups, selecting one of the M groups based on the number of the one or more target devices, and sequentially selecting tracking frequencies included in the selected group, M being less than N.

9. The method of claim 6, wherein the predetermined selection scheme in the operation a) corresponds to a scheme of sequentially selecting M matching switches from the N matching switches, performing the operations b) through g) continuously for each of the M matching switches, and subsequently performing the operations b) through g) continuously for each matching switch, excluding the M matching switches from the N matching switches, M being less than N.

10. The method of claim 1, wherein the generating of the charging power comprises determining the voltage level of the DC voltage to be supplied to the power amplifier based on one or more of a product type of the corresponding target device, a manufacturer information of the corresponding target device, a product model name of the corresponding target device, a battery type of the corresponding target device, a charging scheme of the corresponding target device, an impedance value of the load of the corresponding target device, information about the characteristic of the target resonator of the corresponding target device, information about the used frequency band of the corresponding target device, and an amount of a power to be used for the corresponding target device.

11. The method of claim 1, wherein the generating of the charging power comprises:

generating power for charging by determining the impedance of a source resonator based on the number of the at least one of target device, and adjusting the voltage level of the direct current (DC) voltage to be supplied to the power amplifier based on the number of the at least one of target device.

12. A wireless power transmitter comprising:

a power converter configured to generate a charging power used for charging in at least one of target device, by converting a direct current (DC) voltage to be supplied to a power amplifier to an alternating current (AC) voltage using a resonance frequency;

a source resonator configured to transmit, to at least one of target device, the generated power through magnetic coupling; and

an impedance adjusting unit configured to adjust an impedance of the source resonator based on one or more of a reflected wave of the charging power, an amount of power received by each of the at least one of target device, an amount of the charging power, or a transmission efficiency of the charging power.

13. The wireless power transmitter of claim 12, wherein the impedance adjustment unit is configured to adjust the impedance of the source resonator by controlling N matching switches to be powered ON and OFF, and the impedance adjusting unit comprises the N matching switches which are connected to a plurality of capacitors and/or a plurality of inductors.

14. The wireless power transmitter of claim 12, further comprising a control and communication unit configured to determine the impedance of the source resonator, and a voltage level of the DC voltage to be supplied to the power amplifier based on the number of the at least one of target device, and to control the impedance adjusting unit.

15. The wireless power transmitter of claim 14, wherein the control and communication unit is configured to determine the voltage level of the DC voltage to be supplied to the power amplifier, based on one or more of a product type of a corresponding target device, manufacturer information of the cor-

29

responding target device, a product model name of the corresponding target device, a battery type of the corresponding target device, a charging scheme of the corresponding target device, an impedance value of a load of the corresponding target device, information about a characteristic of a target resonator of the corresponding target device, information about a used frequency band of the corresponding target device, and an amount of a power to be used for the corresponding target device.

16. The wireless power transmitter of claim 14, wherein the control and communication unit is configured to calculate a voltage standing wave ratio (VSWR) based on a voltage level of the reflected wave, a level of an output voltage, and a level of an output current of the source resonator, to control the N matching switches to be powered ON and OFF if the VSWR is less than a predetermined value, to determine a tracking impedance having a power transmission efficiency above a predetermined threshold, and to change the impedance of the source resonator to the tracking impedance having the power transmission efficiency above the predetermined threshold.

17. The wireless power transmitter of claim 16, wherein the control and communication unit is configured to perform the following operations a) through g) continuously for each of the N matching switches in order to determine the tracking impedance having the power transmission efficiency above the predetermined threshold,

- a) selecting at least one of the N matching switches, based on a predetermined selection scheme;
- b) changing the impedance of the source resonator to a selected impedance, by controlling the at least one selected matching switch to be powered ON;
- c) transmitting the charging power;
- d) transmitting, to the at least one of target device, a command to request an input voltage value and an input current value of a target device, or a command to request a DC/DC output voltage value and a DC/DC output current value of the target device;
- e) receiving, from each of the at least one of target device, an input voltage value and an input current value of a rectification unit, or the DC/DC output voltage value and the DC/DC output current value;
- f) calculating an amount of a power received by each of the at least one of target device, based on the input voltage value and the input current value, or the DC/DC output voltage value and the DC/DC output current value; and
- g) calculating a transmission efficiency of the charging power, based on an output voltage level and an output current level of the source resonator, and the amount of a power received by each of the at least one of target device.

18. The wireless power transmitter of claim 17, wherein the predetermined selection scheme in the operation a) corresponds to a scheme of selecting matching switches so that the plurality of capacitors may be powered ON and OFF in a sequential order, beginning from a capacitor having a lowest capacitance value to a capacitor having a highest capacitance value, or a scheme of selecting matching switches so that the plurality of capacitors may be powered ON and OFF in a sequential order, beginning from the capacitor having the highest capacitance value to the capacitor having the lowest capacitance value.

19. The wireless power transmitter of claim 17, wherein the predetermined selection scheme in the operation a) corresponds to a scheme of sequentially selecting M matching switches from the N matching switches, performing the operations b) through g) continuously for each of the M matching switches, and subsequently performing the operations b) through g) continuously for each matching switch, excluding the M matching switches from the N matching switches, M being less than N.

30

20. The wireless power transmitter of claim 17, wherein the predetermined selection scheme in the operation a) corresponds to a scheme of classifying the N matching switches into M groups, selecting one of the M groups based on the number of the at least one of target device, and sequentially selecting matching switches included in the selected group, M being less than N.

21. A wireless power receiver comprising:

a target resonator configured to receive power from a source resonator through magnetic coupling with the source resonator; and

a control and communication unit configured to detect an amount of power received by the target resonator, and to transmit, to a wireless power transmitter, information about the amount of the power received by the target resonator,

wherein an impedance of the source resonator is adjusted based on at least one of a reflected wave of the charging power, an amount of a power received by the target resonator, an amount of the charging power, or a transmission efficiency of the charging power.

22. The wireless power receiver of claim 21, further comprising:

a rectification unit configured to generate a direct current (DC) voltage by rectifying an alternating current (AC) voltage of the power received by the target resonator; and

a DC/DC converter configured to supply a voltage of a predetermined level to a load by adjusting a level of the DC voltage.

23. The wireless power receiver of claim 22, wherein the information about the amount of power received by the target resonator corresponds to an input voltage value and an input current value of the rectification unit, an output voltage value and an output current value of the rectification unit, or a DC/DC output voltage value and a DC/DC output current value.

24. A power receiving method of a wireless power receiver, the method comprising:

receiving power from a wireless power transmitter through magnetic coupling;

receiving a first power used for charging from the wireless power transmitter; and

receiving a second power used for charging, that is generated after an impedance of the source resonator is adjusted in the wireless power transmitter,

wherein the impedance of the source resonator is adjusted based on one or more of at reflected wave of the first power used for charging, an amount of the first power used for charging, or a transmission efficiency of the first power used for charging.

25. The power receiving method claim 24, further comprising:

receiving a wake-up request message from the wireless power transmitter; and

transmitting, to the wireless power transmitter, a response message corresponding to the wake-up request message.

26. The method of claim 25, wherein the response message corresponding to the wake-up request message comprises one or more of a product type of a corresponding target device, manufacturer information of the corresponding target device, a product model name of the corresponding target device, a battery type of the corresponding target device, a charging scheme of the corresponding target device, an impedance value of a load of the corresponding target device, information about a characteristic of a target resonator of the corresponding target device, information about a used frequency band of the corresponding target device, an amount of a power to be used for the corresponding target device, an

intrinsic identifier of the corresponding target device, and product version information or standards information of the corresponding target device.

27. The method of claim 24, wherein the first power used for charging is generated by adjusting a voltage level of a direct current (DC) voltage to be supplied to a power amplifier of the wireless power transmitter. 5

28. The method of claim 24, wherein the adjusted impedance of the source resonator corresponds to a tracking impedance having a power transmission efficiency above a predetermined threshold. 10

29. The method of claim 28, wherein the tracking impedance having the power transmission efficiency above the predetermined threshold is determined by performing the following operations a) through c) continuously for each of the plurality of predetermined tracking impedances, 15

- a) receiving the second power used for charging;
- b) receiving, from the wireless power transmitter, a command to request an input voltage value and an input current value of a target device, or a command to request a DC/DC output voltage value and a DC/DC output current value of the target device; and 20
- c) transmitting, to the wireless power transmitter, an input voltage value and an input current value of a rectification unit, or the DC/DC output voltage value and the DC/DC output current value. 25
